## Database Transactions – Part 2

## ACID Properties

- DBMSs ensure the following properties of transactions.

- Atomicity:**

- The execution of each transaction is atomic, i.e., **either all operations are completed or not done at all.**

- Consistency:**

- The states of a database are consistent (w.r.t. defined business rules) **before and after each transaction.**

- Isolation:**

- Execution results of each transaction should be **unaffected by other concurrent executing transactions.**

- Durability:**

- Once a transaction has been successfully completed, **its effects should persist in the database.**

**Note:** These properties are not independent from one another, but **atomicity is the central property.**

## Atomicity

- **Atomicity** requires that we execute a transaction to completion with only two possibilities:

- **ALL**: all the operations are executed;
- **NONE**: none of the operations are executed.

- If a transaction fails to complete for some reason, it may leave database in an inconsistent state. Thus a DBMS must remove effects of partial transactions to ensure atomicity.

**Example:** The money can only be taken from Steve's account if the money has been transferred into Bob's account.

Operations	Steve	Bob
before 1	\$1000	\$200
after 1	\$1000	\$200
after 2	\$500	\$200
after 3	\$500	\$200
after 4	\$500	\$700

None are executed.

All are executed.

## Atomicity

## Consistency

**Consistency** requires that, each transaction should preserve the consistency of the database.

- Note:** Intermediate states may be inconsistent.

**Example:** Suppose that we have

**Steve's account balance + Bob's account balance = \$1200,**

Operations	Steve	Bob
before 1	\$1000	\$200
after 1	\$1000	\$200
after 2	\$500	\$200
after 3	\$500	\$200
after 4	\$500	\$700

$\$1000 + \$200 = \$1200$

**Not required to be consistent.**

$\$500 + \$700 = \$1200$

## Consistency<sup>1</sup>

# Assignment Project Exam Help

- The database is in a consistent state before and after executing the transaction, but is not necessarily consistent in intermediate states.

<sup>1</sup> The figure is taken from <http://maxdb.sap.com>

## Isolation

# Assignment Project Exam Help

- Isolation requires that transactions are isolated from one another.

**Example:** Other transactions can't see the changes on objects *A* (Steve's account balance) and *B* (Bob's account balance) until the transaction for the money transfer is completed.

$T_1$	$T_2$
read(A)	read(A)
write(A) ( $A := A - 600$ )	write(A) ( $A := A + 400$ )
read(B)	commit
write(B) ( $B := B + 500$ )	
commit	

## Isolation<sup>2</sup>

## Durability

# Assignment Project Exam Help

- **Durability** requires that once the transaction is successfully completed, its changes to the database **must be persistent despite failures**.

- The decision is irrevocable: once committed, the transaction cannot revert to abort. **Changes are durable**.

- **Example:** Once Steve received the notification:  
"\$500 has been successfully transferred to Bob's account",  
the money can't go back to Steve's account and must appear in Bob's account.

## Durability<sup>3</sup>
